**SERIAL COMPRESSED BUS INTERFACE HAVING A REDUCED PIN COUNT**

**1. Technical Field**

The present invention relates generally to digital data communications and, in particular, to a serial compressed bus interface having a reduced pin count.

**2. Background Description**

Conventional serial compressed data buses are dedicated to a single compressed data stream. Moreover, such buses require at least 3 to 4 pins. A typical 3 wire interface consists of a serial data signal, a clock signal and a sync or framing signal. The data is delivered in packets that are of a fixed size and the first bit of a packet is indicated by driving the sync or frame signal active.

An alternate 3 wire interface replaces the sync signal with a valid signal. The valid signal indicates when data is valid on the interface. As with the previous interface, this interface also requires packets to be of a fixed length. The first bit of a packet is indicated by driving the valid signal active. The valid signal is then required to remain active for the duration of a packet and is driven low at the end of the packet. When the valid signal is inactive, the data is ignored by the receiving device. Since the active edge of the valid signal is used to indicate the first bit of a packet, the valid signal must be driven inactive for at least one bit time between packets.

A widely accepted serial transport interfaces uses 4

09715724.1 100021100000

wires to deliver data, clock, sync and valid signals. Like the 3 wire interface, the sync signal is driven active to indicate the first bit of a packet. Similarly, the valid signal is used to identify when data is valid on the 5 interface. This approach gives the added flexibility that data gaps may exist within a packet time. Also, since the sync signal indicates the start of a new packet, there is no requirement for a gap between consecutive packets.

Given the current state of the art, there is a need for 10 a serial compressed data bus that delivers more than one single compressed data stream. Moreover, there is a need for a serial compressed data bus interface having a reduced number of pins with respect to that required by conventional serial compressed data buses.

15

#### **SUMMARY OF THE INVENTION**

The problems state above, as well as other related problems of the prior art, are solved by the present invention, a serial compressed bus interface having a 20 reduced pin count.

The invention advantageously reduces the pin count associated with conventional serial compressed buses by time-division multiplexing a plurality of compressed data streams onto a shared data line. Moreover, the invention 25 advantageously encodes data valid and data request handshake signals rather than using a unique handshake signal pair for each compressed data stream as is done in conventional

000125.19676734.1

serial compressed buses.

These and other aspects, features and advantages of the present invention will become apparent from the following detailed description of preferred embodiments, which is to 5 be read in connection with the accompanying drawings.

#### **BRIEF DESCRIPTION OF THE DRAWINGS**

FIG. 1 is a block diagram of a serial compressed bus and serial compressed bus interface, according to an 10 illustrative embodiment of the invention;

FIG. 2 is a diagram illustrating the encoding of the CB\_DV[2:0] signal, according to an illustrative embodiment of the invention;

FIG. 3 is a diagram illustrating the encoding of the 15 CB\_REQ[3:0] signals, according to an illustrative embodiment of the invention;

FIG. 4 is a timing diagram illustrating the timing relationship of some of the signals of the bus, according to an illustrative embodiment of the invention; and

20 FIG. 5 is a diagram illustrating some of the timing parameters of some of the signals of the bus, according to an illustrative embodiment of the invention.

#### **DETAILED DESCRIPTION OF PREFERRED EMBODIMENTS**

It is to be understood that the present invention may 25 be implemented in various forms of hardware, software, firmware, special purpose processors, or a combination thereof. Preferably, the invention is implemented as a

combination of hardware and software.

It is to be further understood that, because some of the constituent system components depicted in the accompanying Figures may be implemented in software, the 5 actual connections between the system components may differ depending upon the manner in which the present invention is programmed. Given the teachings herein, one of ordinary skill in the related art will be able to contemplate these and similar implementations of the present invention.

10 FIG. 1 is a block diagram of a serial compressed bus 100 and a serial compressed bus interface 199, according to an illustrative embodiment of the invention. In the illustrative embodiment, serial data enters an integrated circuit through the bus 100. The bus 100 is implemented 15 with a single serial data line that is time multiplexed between each of a plurality of data sources. Packet data from the different data sources is interleaved onto the single serial data line on byte boundaries. Each of the data sources is delivered to one or more data consumers in 20 the receiving application device. As used herein, the term Application@ refers to a consumer or processor of a compressed data stream, such as, for example, an MPEG2 video decoder or an AC-3 audio decoder.

25 To support decoding and presentation of multiple concurrent audio and video streams, the bus 100 will have support for up to seven separate application decoders. That is, the bus 100 can deliver seven compressed data streams

corresponding to seven application decoders. It is to be appreciated that while the illustrative embodiment of FIG. 1 shows the use of seven compressed data streams the invention is not so limited and, thus, any feasible number of 5 compressed data streams may be employed in accordance with the invention, while maintaining the spirit and scope thereof.

In the current state of the art, seven compressed data streams would be delivered over seven compressed data 10 interfaces. Each of these interfaces would normally consist of at least three signals, requiring a total of 21 signals for seven compressed data streams. According to the invention, the bus 100 delivers the seven compressed data streams through nine external signals: CB\_CLK; CB\_DATA; 15 CB\_DV[2:0]; and CB\_REQ[3:0]. The pin count of the bus 100 is reduced by a time-division multiplexing of the seven compressed data streams onto a shared data line. The pin count of the bus 100 is also lowered by encoding DV (data valid) and REQ (data request) handshake signals rather than 20 using a unique handshake signal pair for each compressed data stream.

The bus 100 includes the following five inputs: CB\_CLK; CB\_DATA; and CB\_DV[2:0]. The CB\_CLK signal is the compressed bus serial clock, which supports a maximum speed 25 of 100MHz. The CB\_DATA signal is the compressed bus serial data, which is valid on the rising edge of CB\_CLK. The CB\_DV[2:0] signals indicate that data on CB\_DATA is valid

for one of the seven supported application devices.

Each of the BUF\_FULL[6:0] signals represents a compressed data buffer. It is to be appreciated that the phrase A compressed data buffer@ and the term AFIFO@ (First-In-First-Out) are used interchangeably herein. When one of the BUF\_FULL[6:0] signals is set to A1", it indicates that the corresponding compressed data buffer is full and cannot accept more data.

5 The bus 100 includes the following output: CB\_REQ[3:0].  
10 The CB\_REQ[3:0] signals correspond to a request from at least one of the application devices.

15 Each of the BUF\_SEL[6:0] signals represents an application device. When one of the BUF\_SEL[6:0] signals is set to A1", it indicates that data will be removed from the application specific FIFO and sent to a common transport demultiplexing circuit 150.

20 A bus interface circuit 199 includes a serial-to-parallel converter 110, enable logic 112, and a request control circuit 114. The bus interface circuit 199 is coupled to a plurality of compressed data buffers 130-136 which, in turn, are coupled to main memory through a multiplexor 140 and transport de-multiplexor 150. Signals from the converter 110, enable logic 112, and the request control circuit 114 are used to write to the plurality of 25 compressed data buffers 130-136.

The serial-to-parallel converter 110 converts serial data to parallel data. The serial data is time-division

multiplexed and is input by the CB\_DATA signal. The parallel data is 8-bits (1-byte) wide and is output by the CDATA signal. The CDATA signal is provided to the plurality of compressed data buffers 130-136.

5 The enable logic 112 selects a particular compressed data buffer to which data is to be written, based on the CB\_DV[2:0] signal input thereto. Accordingly, the enable logic 112 outputs the BUF\_SEL[6:0] signals.

10 The request control circuit 114 inputs the BUF\_FULL[6:0] signals and outputs the CB\_REQ[3:0] signals. Thus, the request control circuit 114 indicates when one or more of the compressed data buffers 130-136 is full and, thus, no additional data can be written thereto.

15 As noted above, the CB\_DV[2:0] signals are used to indicate that valid data is present on CB\_DATA for one of the seven application FIFOs 130-136. FIG. 2 is a diagram illustrating the encoding of the CB\_DV[2:0] signal, according to an illustrative embodiment of the invention. The encoding has been chosen such that an external IC that 20 supports three separate strobe signals to strobe data into the video decoder could be made to work with the bus 100 and still support two compressed video streams and one compressed audio stream. The CB\_DV[2:0] signals will change state on the rising edge of the CB\_CLK signal. The 25 CB\_DV[2:0] signals will hold a state for a minimum of eight CB\_CLK cycles and a multiple of eight CB\_CLK cycles. The data present on the CB\_DATA signal can only be valid for one

application FIFO at a time.

As noted above, the serial data for each application is converted into byte wide parallel format and transferred to the appropriate compressed data buffer. There is one FIFO (one of FIFOs 130 though 136) implemented for each application device. It is to be appreciated that the aggregate data rate received for all application devices should not exceed the sum total of the maximum data rate of all of the input channels.

10 The CB\_REQ[3:0] signals are used to request compressed data for each of the application devices 130-136. When there is space available in an application=s FIFO, the corresponding CB\_REQ line will be driven high. When there is no space available in an application=s FIFO, the corresponding CB\_REQ line will be driven low. Several of the CB\_REQ[] lines may be high at the same time.

15 In the illustrative embodiment of this invention, CB\_REQ[3:0] can uniquely identify requests for data from as many as four unique application devices. In this embodiment it is to be understood that four of the application devices are grouped such that they share a single CB\_REQ line. However, it is to be appreciated that the invention does not require any specific grouping of application devices or sharing of CB\_REQ lines among application devices. Given 20 the teachings of the invention provided herein, one of ordinary skill in the related art would readily contemplate a different grouping of application devices to share the

available CB\_REQ lines, or implementations of the invention that allow a request from each application device to be uniquely identified. FIG. 3 is a diagram illustrating the encoding of the CB\_REQ[3:0] signals, according to the 5 illustrative embodiment of the invention.

The CB\_REQ[1] signal maps to the PIP/record channel video. It is possible within a system for multiple videos to be present on a single broadcast transponder. To allow the simultaneous decode of up to four videos present on a 10 single transponder, the CB\_REQ[1] signal is actually mapped to four separate compressed data buffers. When all of the compressed data buffers mapped to the CB\_REQ[1] signal are ready to accept data, then the CB\_REQ[1] signal is driven high. If any of the buffers mapped to the CB\_REQ[1] signal 15 are not ready to receive data, then the CB\_REQ[1] signal is held low. If the data carried by the transponder is not multiplexed in a way that will allow simultaneous video decode of all videos present, then it is possible to underflow one or more of the bit buffers serviced by 20 CB\_REQ[1]. No provision will be made in this block to recover from this condition. However, given the teachings of the invention provided herein, one of ordinary skill in the related art will readily contemplate various modified configurations of the bus 100 which maintain the spirit and 25 scope of the invention while allowing for recovery from underflow conditions. FIG. 4 is a timing diagram illustrating the timing relationship of some of the signals

of the bus 100, according to an illustrative embodiment of the invention. FIG. 5 is a diagram illustrating some of the timing parameters of some of the signals of the bus 100, according to an illustrative embodiment of the invention.

5        Although the illustrative embodiments have been described herein with reference to the accompanying drawings, it is to be understood that the present system and method is not limited to those precise embodiments, and that various other changes and modifications may be affected  
10      therein by one skilled in the art without departing from the scope or spirit of the invention. All such changes and modifications are intended to be included within the scope of the invention as defined by the appended claims.

03716723.1.12000

**WHAT IS CLAIMED IS:**

1. A serial compressed bus interface, comprising:  
a serial-to-parallel converter having a single serial  
5 data input line adapted to receive time-division multiplexed  
serial data from a plurality of data sources; and  
enable logic adapted to input at least one data valid  
signal that identifies each of a plurality of data consumers  
for which the time-division multiplexed serial data is  
10 valid.

2. The serial compressed bus interface according to  
claim 1, wherein said serial-to-parallel converter is  
further adapted to convert the time-division multiplexed  
15 serial data to parallel data, and to output the parallel  
data to the plurality of data consumers.

3. The serial compressed bus interface according to  
claim 1, further comprising a request control circuit  
20 adapted to output at least one request signal that requests  
the time-division multiplexed serial data for at least one  
of the plurality of data consumers.

25 4. The serial compressed bus interface according to  
claim 3, further comprising at least one encoder adapted to  
encode at least one of the at least one data valid signal

and the at least one request signal to correspond to more than one of the plurality of data consumers.

5. The serial compressed bus interface according to  
5 claim 3, wherein the request control circuit is further  
adapted to encode the at least one request signal to  
correspond to more than one of the plurality of data  
consumers.

10 6. A method for transmitting serial compressed data  
from a plurality of data sources to a plurality of data  
consumers, comprising the steps of:

time-division multiplexing the serial compressed data  
from the plurality of data sources to generate time-division  
15 multiplexed serial compressed data; and  
transmitting the time-division multiplexed serial  
compressed data to the plurality of data consumers.

7. The method according to claim 6, wherein said  
20 transmitting step transmits the time-division multiplexed  
serial compressed data on a single data line.

8. The method according to claim 6, further  
comprising the step of encoding a data valid signal to  
25 indicate that the time-division multiplexed serial  
compressed data is valid for more than one of the plurality  
of data consumers.

9. The method according to claim 6, further comprising the step of encoding a request signal to indicate that the time-division multiplexed serial compressed data is  
5 requested by more than one of the plurality of data consumers.

10. A method for transmitting serial compressed data from a plurality of data sources to a plurality of data  
10 consumers, comprising the steps of:  
interleaving serial compressed packet data from the plurality of data sources to generate time-division multiplexed serial compressed data; and  
transmitting the time-division multiplexed serial  
15 compressed data to the plurality of data consumers.

**COMPRESSED SERIAL BUS**

**Abstract**

There is provided a serial compressed bus interface  
5 having a reduced pin count. The interface includes a  
serial-to-parallel converter having a single serial data  
input line adapted to receive time-division multiplexed  
serial data from a plurality of data sources. Enable logic  
is adapted to input at least one data valid signal that  
10 identifies each of a plurality of data consumers for which  
the time-division multiplexed serial data is valid.
